ABSTRACT

This report presents the results of groundwater monitoring activities conducted within Waste Area Group 2 at the Idaho National Laboratory during Fiscal Year 2006.

Groundwater samples were collected from eight perched water wells and seven Snake River Plain Aquifer wells. Groundwater sampling events took place in October 2005 and March 2006. Groundwater samples were analyzed for chromium (filtered and unfiltered), tritium, Sr-90, and gamma-emitting isotopes. In addition, groundwater samples were analyzed for gross alpha and gross beta in the March 2006 sampling event. Using an interface probe, the thickness of a floating organic layer at the water table was monitored at three perched water wells.

In perched water well samples, tritium and Sr-90 were detected above their respective maximum contaminant levels. Tritium was detected above its maximum contaminant level of 20,000 pCi/L in Wells PW-11 and PW-9. Sr-90 occurred above its maximum contaminant level of 8 pCi/L in perched wells PW-12, TRA-1933, TRA-1934, USGS-054, USGS-055, and USGS-056. Although previously above its maximum contaminant level, the Co-60 concentration in Well PW-12 has declined to 17.8 pCi/L, which is well below the maximum contaminant level of 200 pCi/L.

In the filtered aquifer well samples, chromium was detected above its maximum contaminant level, 100 µg/L, in Well TRA-07 at a concentration of 133 µg/L. In the past, USGS-065 had filtered chromium concentrations greater than the maximum contaminant level. Except for the Highway-3 well, however, chromium concentrations in aquifer wells sampled were above background levels. Sr-90 was above its maximum contaminant level of 8 pCi/L in the Highway-3 well and TRA-07 in October 2005. However, these occurrences are suspect, because Sr-90 was not detected in the Highway-3 well in subsequent sampling events and there were quality control concerns with the Sr-90 data for October 2005. All other constituents were below maximum contaminant levels, although tritium concentrations were above background concentrations in all aquifer wells except Highway-3.

Annual Groundwater Monitoring Status Report for Waste Area Group 2 for Fiscal Year 2006

1. INTRODUCTION

Samples from the Snake River Plain Aquifer (SRPA) and perched water beneath Waste Area Group (WAG) 2 at the Idaho National Laboratory (INL) (Figure 1-1) were collected and analyzed during Fiscal Year (FY) 2006 in accordance with the *Groundwater Monitoring Plan for the Test Reactor Area Operable Unit 2-13* (DOE-ID 2004a). Groundwater monitoring being conducted satisfies some of the requirements in the *Final Record of Decision for Test Reactor Area for Operable Unit 2-13 at the Idaho National Engineering and Environmental Laboratory* (DOE-ID 1997) and the *Record of Decision for the Test Reactor Area Perched Water System, Operable Unit 2-12* (DOE-ID 1992).

1.1 Purpose

This document presents and summarizes groundwater sample data collected during FY 2006 for the wells covered under the groundwater monitoring plan (DOE-ID 2004a). Samples were collected from seven wells completed in the SRPA and eight wells completed in perched water bodies above the SRPA. Sampling was conducted to (a) evaluate contaminant concentrations in the deep perched water system and the SRPA after discharge to the former warm waste ponds was eliminated, (b) verify the accuracy of SRPA contaminant concentration trends predicted by computer modeling, and (c) verify that groundwater concentrations have not increased to unacceptable levels.

The data presented here supplement groundwater monitoring data presented in the five-year review reports (DOE-ID 2003; DOE-ID 2006) and previous annual monitoring reports (INEEL 2003; DOE-ID 2004b; ICP 2005). Information regarding water quality and contaminant concentrations and trends is presented in Section 2. Recommendations are presented in Section 3.

Groundwater monitoring at WAG 2 will continue until the U.S. Department of Energy Idaho Operations Office, the U.S. Environmental Protection Agency (EPA), and the Idaho Department of Environmental Quality determine that monitoring is no longer necessary based on results from a five-year review.

1.2 Groundwater Monitoring Activities

The groundwater monitoring plan (DOE-ID 2004a) calls for collecting groundwater samples twice a year in October and March. In FY 2006, the October 2005 sampling event carried over into November and the March 2006 sampling event ran into April. According to the monitoring plan, groundwater samples are to be collected from perched water wells PW-11, PW-12, PW-14, USGS-053, USGS-054, USGS-055, TRA-1933, TRA-1934, and USGS-056 in October and March of each year. Table 1-1 summarizes the construction details for each of the WAG 2 groundwater monitoring wells. However, no samples were collected from perched water well PW-14, because it was dry in October 2005 and March 2006. Well USGS-056 was only sampled in October 2005, because it was dry during the March 2006 sampling event. The amount of water in USGS-053 was too low to be sampled in October 2005 and March 2006. In accordance with the groundwater monitoring plan (DOE-ID 2004a), Well PW-9 was sampled instead of USGS-053 in March 2006. Well PW-13 could not be sampled in October 2005 due to a plugged pump and was not sampled in March 2006 due to low water level. Well TRA-1933 was not sampled in October 2005 because the pump was not functioning. The pump in TRA-1933 has been replaced with a new pump and will be sampled in the next round.

Wells PW-13, TRA-1933, and TRA-1934 were monitored with an interface probe to ascertain the presence and thickness of a floating organic layer. In addition, petro (petroleum) traps placed in PW-13, TRA-1933, and TRA-1934 were monitored on a monthly basis for free-phase product.

Groundwater samples are also required from aquifer wells TRA-06, TRA-07, TRA-08, USGS-058, USGS-065, MIDDLE-1823, and Highway-3. Well TRA-08 was not sampled in March 2006, because the water level was too low.

Water levels were measured prior to sampling each well. It is anticipated that data gathered from the WAG 10 automated network will be used to construct a water table map for the Reactor Technology Complex (RTC) area in FY 2007.

2. MONITORING RESULTS

This section presents the analytical results for the perched water and SRPA wells. With the exception of analyses for radionuclides, samples were analyzed in accordance with established INL and EPA methods; radionuclide analyses were performed in accordance with the “Idaho National Engineering and Environmental Laboratory Sample and Analysis Management Statement of Work for Analytical Services” (ER-SOW-394). That statement of work establishes the minimum required detection limits and quality assurance requirements for the analytical methods to be employed. All analytical results were validated to resident procedures established by INL Sample and Analysis Management (SAM). Table 2-1 summarizes the sample data from FY 2006. Complete sampling results are presented in Appendix A. The quality assurance and control sample results are discussed in Appendix B.

2.1 Perched Water Well Sampling Results

Perched water samples were analyzed for chromium (filtered and unfiltered), Sr-90, tritium, and gamma-emitting isotopes. In addition, samples were analyzed for gross alpha and gross beta in the March 2006 sampling event. When radiological results are reported in the text of this document, only the concentrations are given; the associated uncertainties are listed in Table 2-1 and Appendix A. In addition, two wells, TRA-1933 and TRA-1934, were analyzed for gasoline range organics (GROs) and diesel range organics (DROs). Results for the above constituents are summarized in the following subsections. In the subsections below, sample concentrations in perched wells are compared with maximum contaminant levels (MCLs); however, these comparisons are not intended to imply that the perched water bodies represent an aquifer that is conducive to long-term use.

2.1.1 Chromium

Filtered chromium analytical results from the perched water wells were below the EPA-defined MCL of 100 µg/L, although the result for one sample from Well USGS-056 was very close at 99.7 µg/L. In addition to USGS-056, filtered chromium concentrations exceeded background concentrations in Wells PW-9, PW-11, USGS-055, and TRA-1934. Figure 2-1 shows filtered chromium concentrations in the individual wells (perched and aquifer) from October 2005 and March 2006. Unfiltered chromium concentrations in the perched wells exceeded 100 µg/L in Well USGS-056.

2.1.2 Gamma-emitting Isotopes

Two gamma-emitting isotopes (Co-60 and Ra-226) were present at detectable concentrations during the FY 2006 sampling. Co-60 was detected in one sample from Well PW-12. Ra-226 was detected in the sample from Well TRA-1934 in the October 2005 sampling event, but it was not detected in any perched wells in the March 2006 sampling event.

Although the reported concentration of Ra-226 exceeded the EPA-defined MCL of 5 pCi/L for Ra-226/Ra-228, Ra-226 results were obtained by direct gamma spectrometry and are flagged with “J” validation flags as estimated values. General Engineering Laboratories quantifies Ra-226 using Bi-214 daughter photopeak at 609 keV. It is not possible to quantify Ra-226 by spectrometry without a separate analysis to allow time for the ingrowth and equilibration of radon daughter products. Therefore, sample results are not considered representative of radium concentrations in the groundwater. In addition, Ra-226 was detected in the field blank and equipment rinsate at concentrations near that detected in TRA-1934. The spurious nature of the Ra-226 results also was confirmed by the gross alpha results from the March 2006 sampling event presented below. The gross alpha results cast doubt on the Radium-226 results since they are not elevated, as they are expected to be if radium-226 was indeed in the samples.

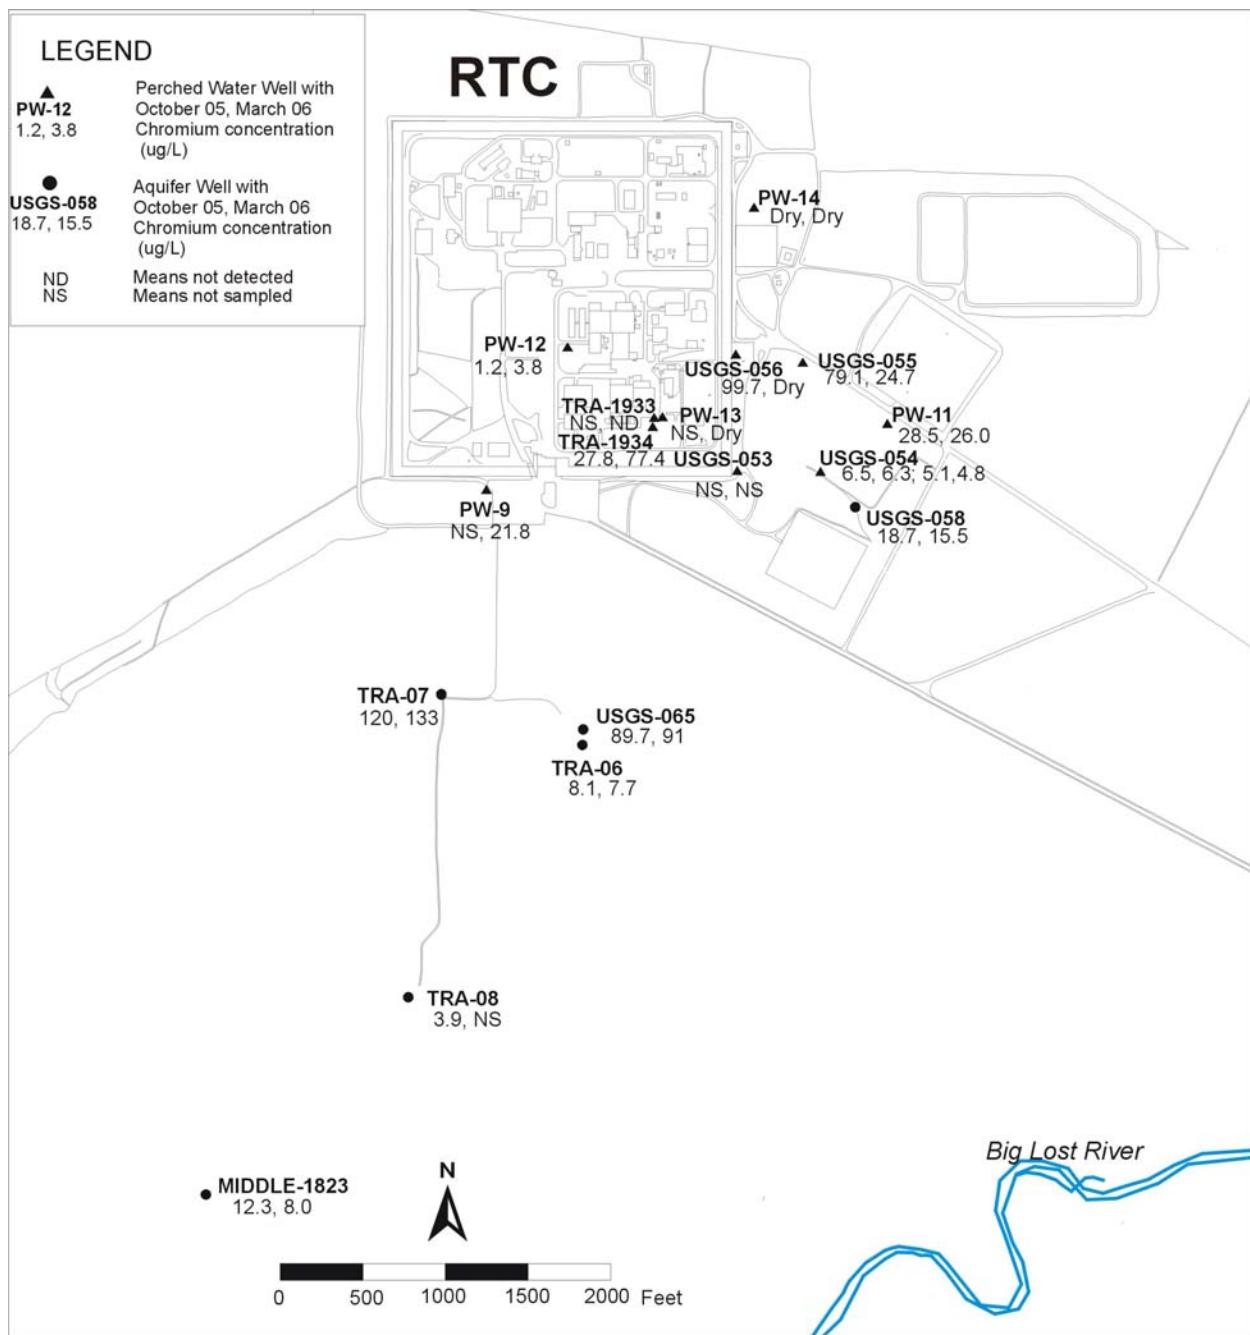

Figure 2-1. Chromium concentrations ($\mu\text{g/L}$) for October 2005 and March 2006.

Co-60 was detected in one sample from Well PW-12 at concentrations of 17.8 pCi/L in October 2005. Co-60 was not present at detectable concentrations in any of the other wells. The Co-60 detection is well below its EPA-defined MCL of 200 pCi/L. The Co-60 concentration in PW-12 continues to decline from the previous years' results, as shown in Figure 2-2. In addition, other gamma constituents that would generally be expected to accompany Co-60 (for example, Cm-144 and Cs-137) were not present in PW-12. The minimum detectable activity for Co-60 during the FY 2006 sampling was generally between 9 and 16 pCi/L with the minimum detectable activity (MDA) for each sample included in Appendix A.

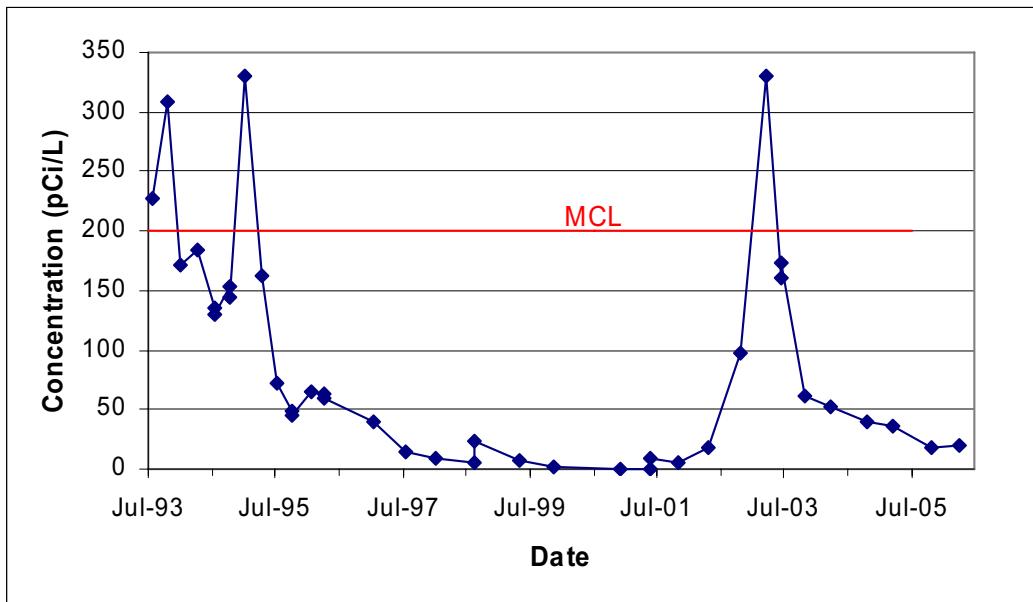

Figure 2-2. Co-60 concentration (pCi/L) in PW-12.

2.1.3 Strontium-90

Sr-90 results ranged from nondetect to 100 pCi/L in the perched water wells sampled (Table 2-1). Wells PW-12, TRA-1933, TRA-1934, USGS-054, USGS-055, and USGS-056 exceeded the EPA-defined MCL of 8 pCi/L. The highest Sr-90 concentration, 100 pCi/L, occurred in the March 2006 sample from TRA-1934. The minimum detectable activity for Sr-90 generally was between 0.6 and 3 pCi/L. Figure 2-3 shows Sr-90 concentrations in the perched wells.

The Sr-90 concentration trends indicate that concentrations are decreasing in USGS-054 and USGS-056 (Figure 2-4). In contrast, the concentration data for PW-12 and USGS-055 indicate an overall positive trend. The cyclic nature of the increase in Sr-90 concentration in PW-12 seems to reflect pulses of contamination moving through the well. Wells TRA-1933, and TRA-1934 have not been sampled for Sr-90 a sufficient number of times to allow examination of data trends.

2.1.4 Tritium

Tritium is present at detectable concentrations in five of the eight perched wells sampled; however, it only exceeds the 20,000 pCi/L MCL in Wells PW-11 and PW-9 (Table 2-1 and Figure 2-5). The highest tritium concentration was in PW-9 at 36,800 pCi/L. Tritium concentrations in PW-11 were 28,100 pCi/L in October 2005 and 29,500 pCi/L in March 2006. The tritium concentrations for Well PW-11 show a statistically significant trend of decreasing concentrations, with a correlation coefficient of 0.948 (Figure 2-6). The minimum detectable activity for tritium ranged from 172 to 424 pCi/L for the FY 2006 sampling. The minimum detectable activity for each sample is included in Appendix A.

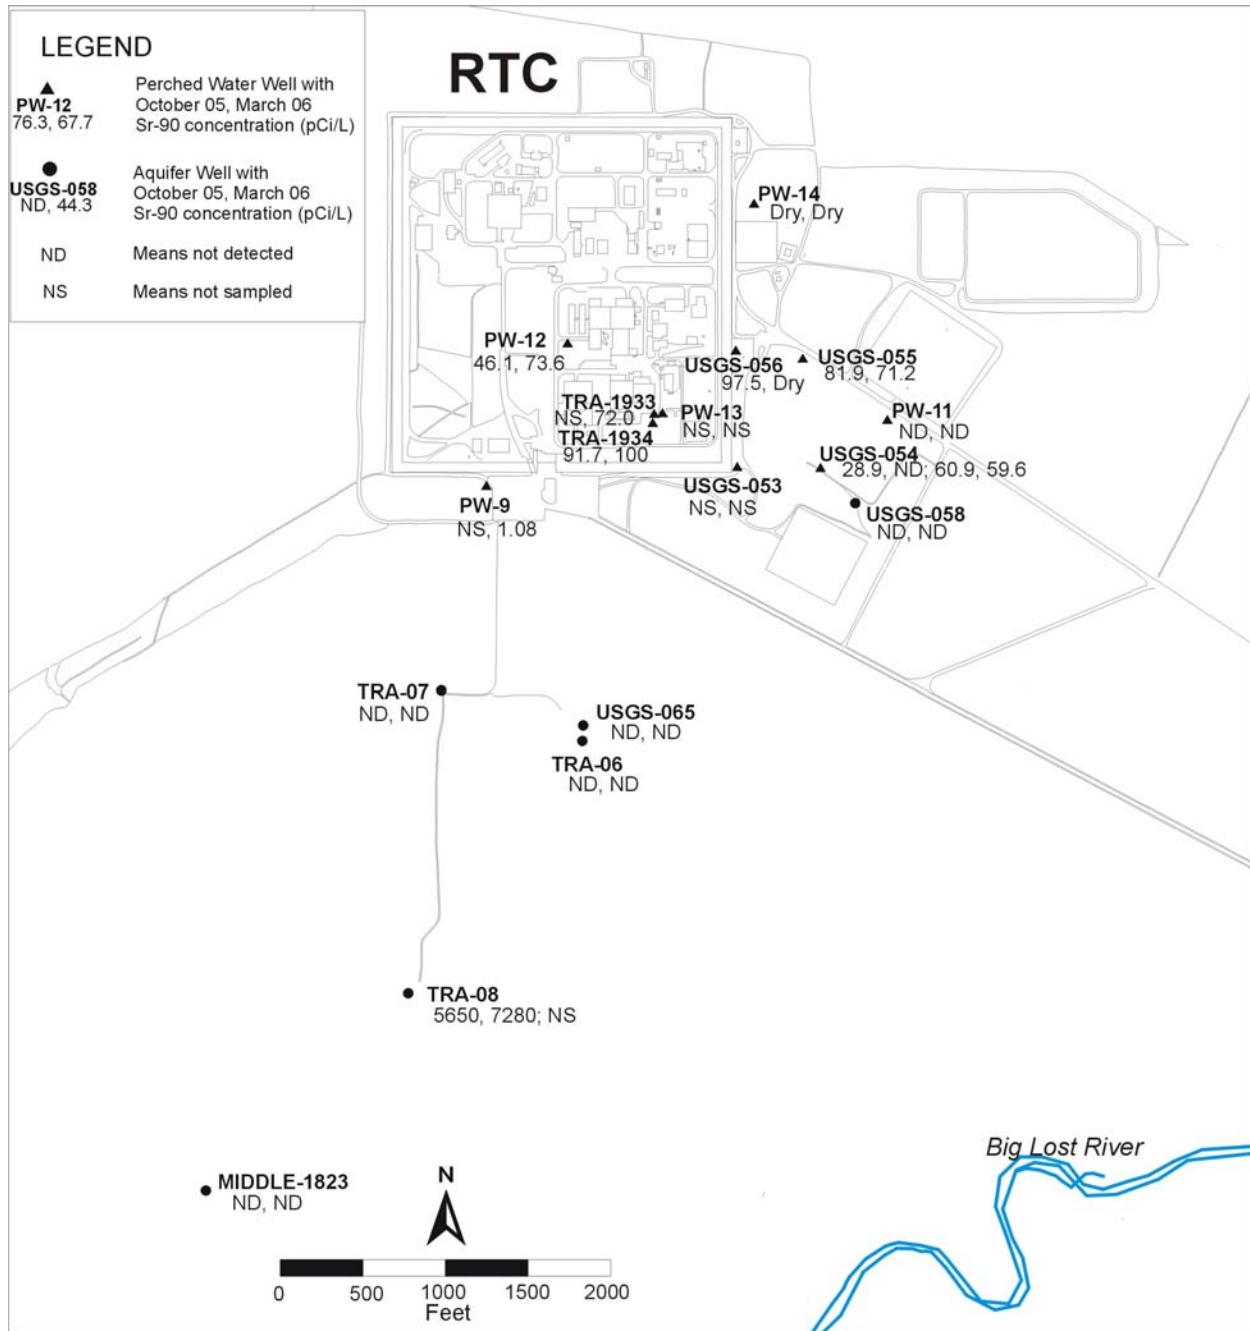

Figure 2-3. Sr-90 concentrations (pCi/L) for October 2005 and March 2006.

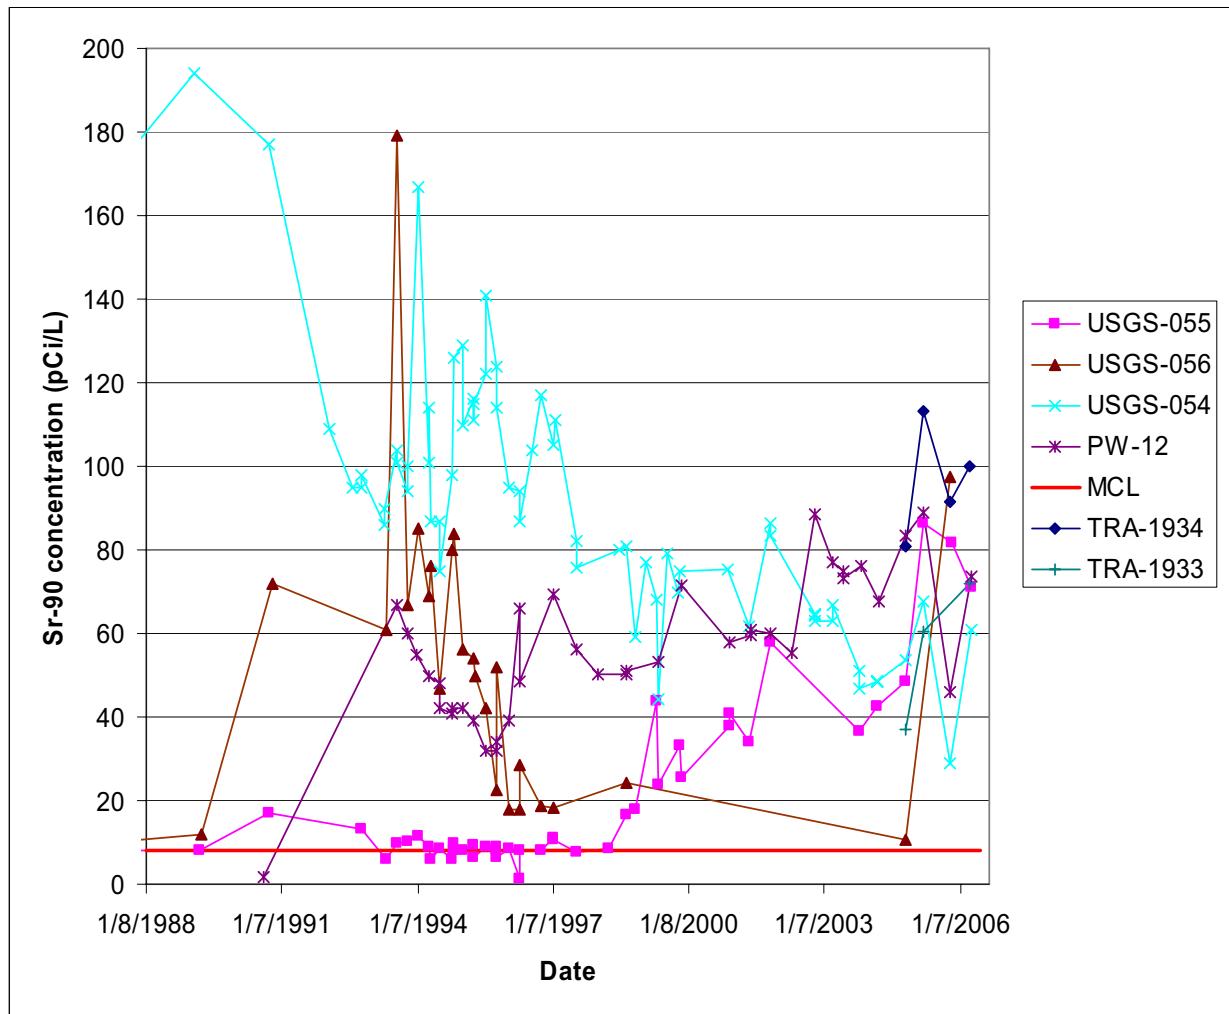

Figure 2-4. Sr-90 concentration trends (pCi/L) in PW-12, USGS-054, USGS-055, and USGS-056.

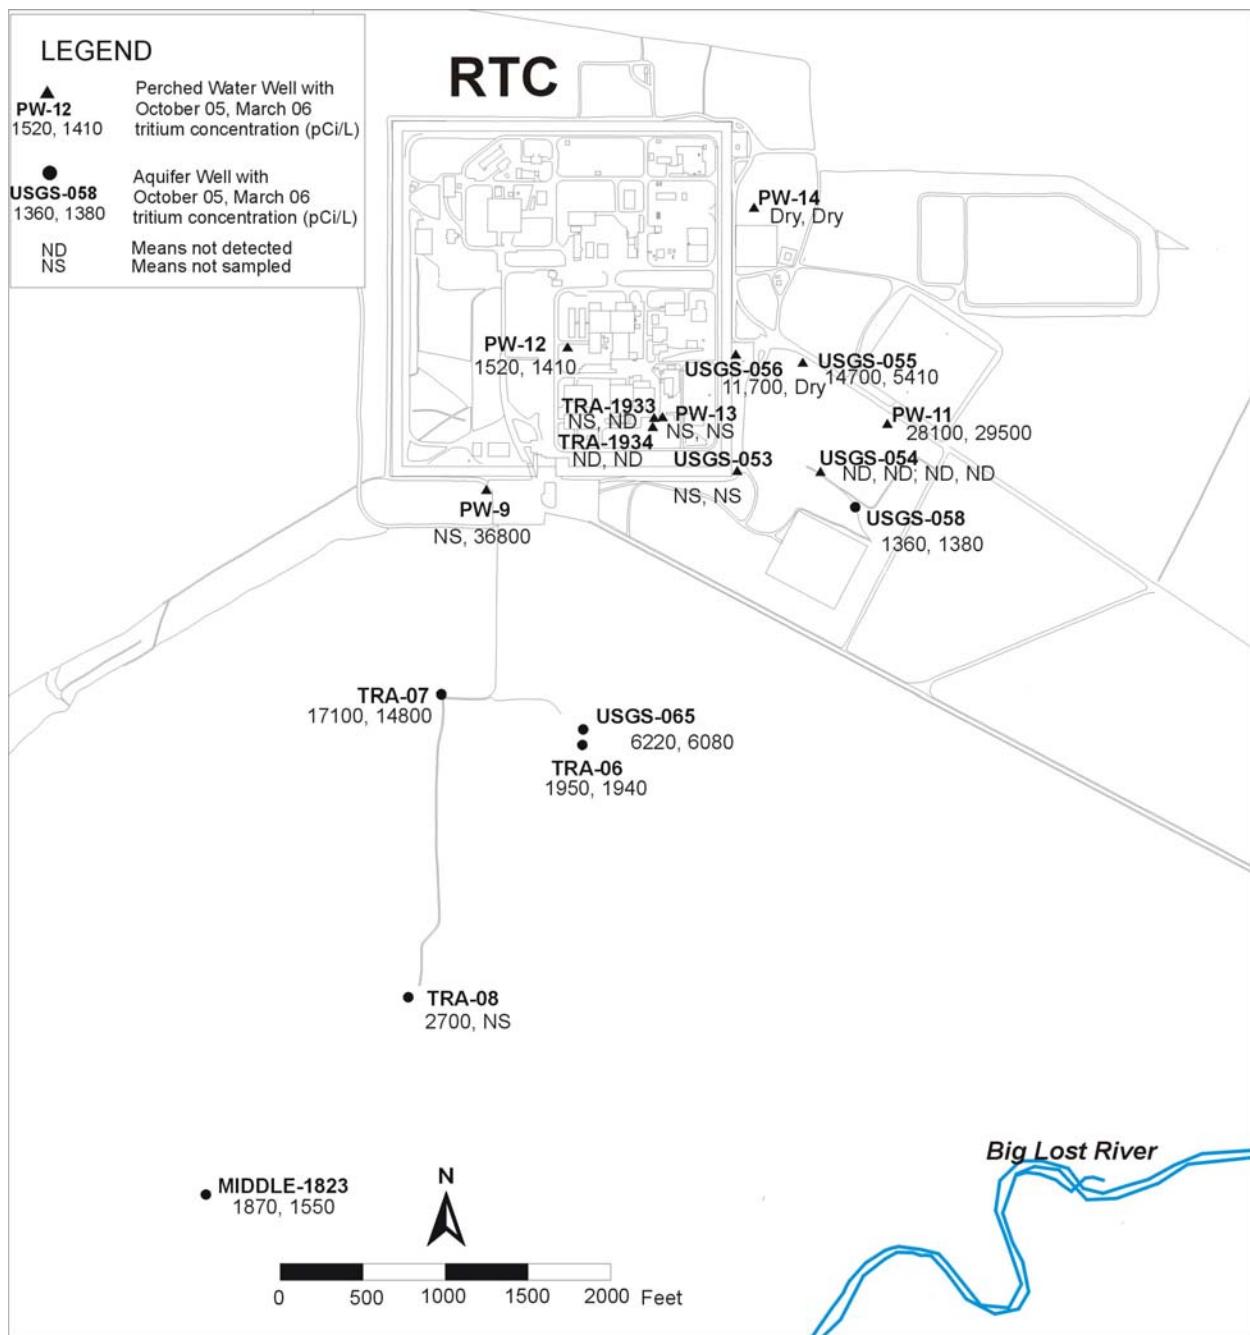

Figure 2-5. Tritium concentrations (pCi/L) for October 2005 and March 2006.

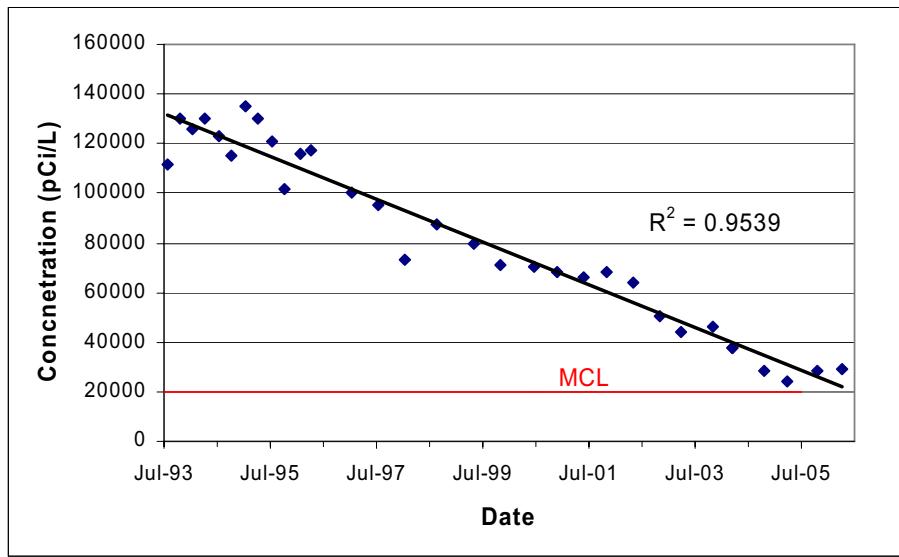

Figure 2-6. Tritium concentrations (pCi/L) in PW-11.

2.1.5 Gross Alpha and Gross Beta

Gross alpha and gross beta analysis were added for the March 2006 sampling event because of the reported elevated strontium-90 and radium-226 detections. Gross beta results correlated with Sr-90 results, with the highest Sr-90 and gross beta concentrations occurring in TRA-1934. Gross alpha results were all below the MCL of 15 pCi/L with the maximum detected concentration of 7.46 pCi/L occurring in PW-9 (Table 2-2).

Table 2-2. Gross alpha and gross beta results for Waste Area Group 2 wells.

2.1.6 Diesel Range Organic and Gasoline Range Organic Results

Samples for DROs and GROs were collected from Wells PW-12, TRA-1933, and TRA-1934 (Table 2-3). Samples could not be collected from PW-13 because of pump problems and lower water level. The highest DRO (1.5 mg/L) and GRO (127 µg/L) concentrations were in TRA-1933. The DRO and GRO concentrations were the lowest in PW-12.

Table 2-3. Organic analyte results for Waste Area Group 2 perched wells.

2.2 Aquifer Well Sampling Results

Groundwater samples were collected from aquifer wells TRA-06, TRA-07, USGS-058, USGS-065, MIDDLE-1823, and Highway-3. Well TRA-08 was not sampled in either October 2005 or March 2006 because of pump problems. Aquifer wells were analyzed for chromium (filtered and unfiltered), Sr-90, gamma isotopes, and tritium. In March 2006, samples were also collected for gross alpha and gross beta analyses. The results for the analytes are summarized in the following subsections. The results for tritium, Sr-90, and chromium are summarized in Table 2-1. Comparison to background concentrations at the INL and comparison to MCLs for detected analytes are summarized in Table 2-4.

Table 2-4. Waste Area Group 2 groundwater quality summary.

Analyte	Background ^a	Maximum	Minimum	Wells above MCL	MCL
<i>Perched Water Wells</i>					
Chromium Filtered	2 to 3	99.7	ND	0	100 µg/L
Chromium Unfiltered	NA	101	ND	1	100 µg/L
Co-60	0	17.8	ND	0	200 pCi/L
Ra-226	0	154	ND	1	5 pCi/L ^b
Sr-90	0	100	ND	6	8 pCi/L

Table 2-4. (continued).

Analyte	Background ^a	Maximum	Minimum	Wells above MCL	MCL
Tritium	75 to 150	36,800	ND	2	20,000 pCi/L
Gross alpha	0 to 3	7.46	ND	0	15 pCi/L
Gross beta	0 to 7	176	9.21	NA	4 mrem/yr
<i>Aquifer Wells</i>					
Chromium Filtered	2 to 3	133	ND	2	100 µg/L
Chromium Unfiltered	NA	143	ND	2	100 µg/L
Sr-90	0	7280	ND	2	8 pCi/L
Ra-226	0	116	ND	1	5 pCi/L ^b
Tritium	75 to 150	17,100	ND	0	20,000 pCi/L
Gross alpha	0 to 3	6.64	ND	0	15 pCi/L
Gross beta	0 to 7	8.96	ND	NA	4 mrem/yr

a. Background concentrations are from Knobel, Orr, and Cecil (1992).

b. Represents MCL for Ra-226 and Ra-228 combined.

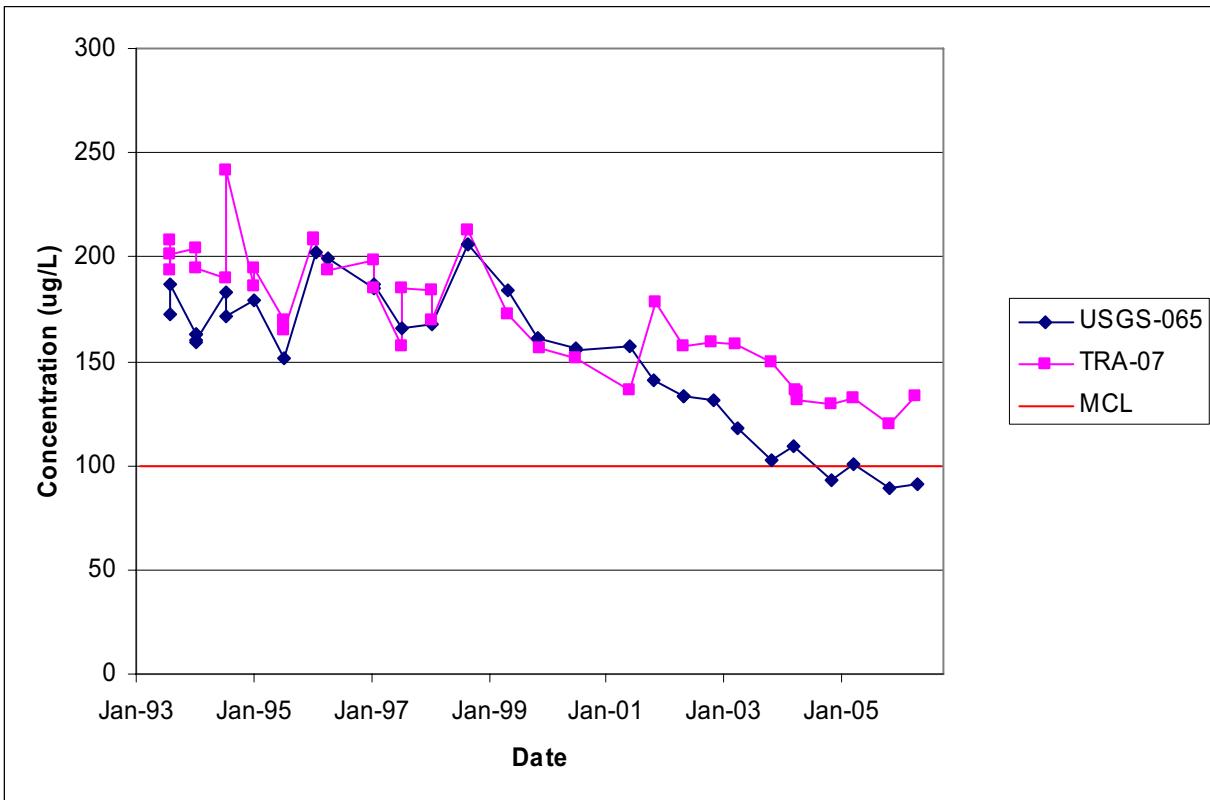

MCL = maximum contaminant level

ND = not detected

NA = not applicable

2.2.1 Chromium

Chromium was detected in all but three filtered samples and one unfiltered sample. Filtered chromium concentrations were above the EPA-defined MCL of 100 µg/L only in Well TRA-07 (Table 2-1 and Figure 2-1). Analytical results for TRA-07 indicated a filtered chromium concentration of 120 µg/L in October 2005 and 133 µg/L in March 2006. Although previously above the MCL, the FY 2006 results for Well USGS-065 showed filtered chromium concentrations of 89.7 µg/L in October 2005 and 91 µg/L in March 2006. Wells TRA-07 and USGS-065 appear to show decreasing trends in chromium concentrations since 1999 (Figure 2-7).

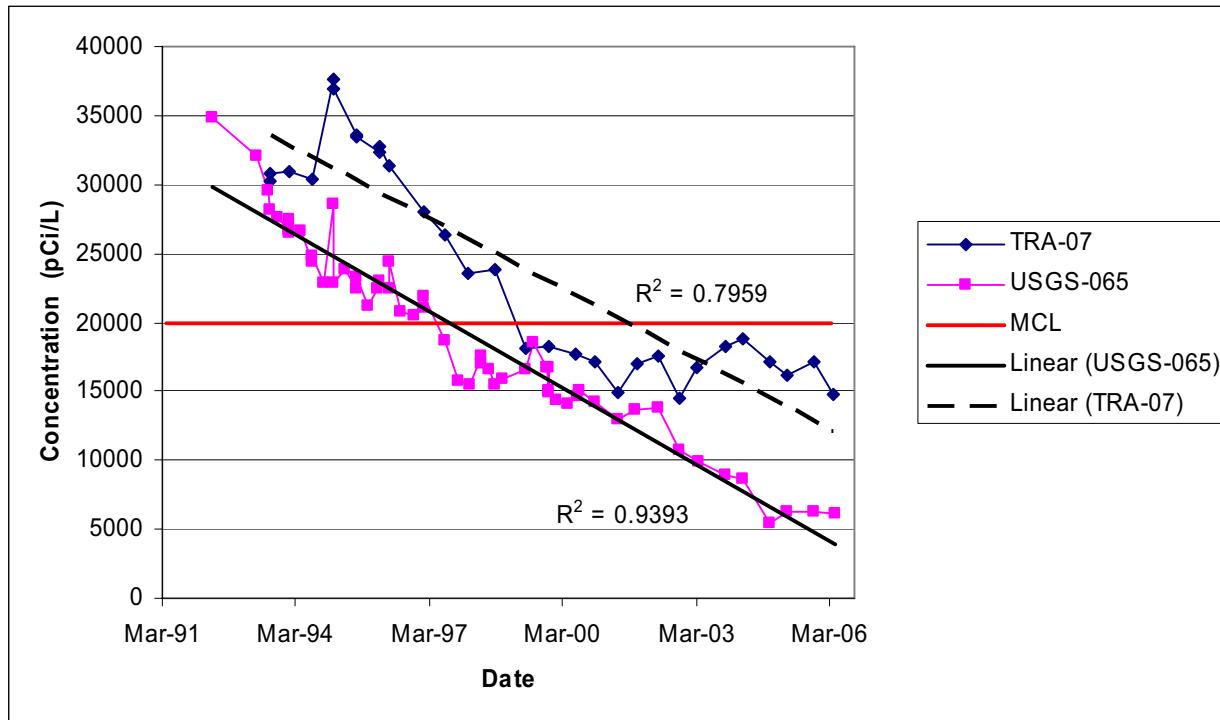

Figure 2-8. Tritium concentration trends in TRA-07 and USGS-065.

2.2.4 Gamma Spectrometry

Two gamma-emitting isotopes (Ra-226 and Cs-134) were detected by gamma spectrometry during the FY 2005 sampling events. In October 2005, Ra-226 was detected in Well USGS-065 at 116 pCi/L. However, this Ra-226 detection is suspect since it was not detected in the March 2006 sampling event and for the reasons given in Subsection 2.1.2.

Cs-134 was detected in only one sample at a concentration of 10.5 pCi/L. Cs-134 was reported in the October 2005 sampling event from TRA-08. The detection is suspect since Cs-137 was below detection limits in TRA-08. This Cs-134 occurrence is probably a statistical anomaly associated with the analytical method.

2.2.5 Gross Alpha and Gross Beta

Gross beta analysis was added for the March 2006 sampling event because of the sporadic recent strontium-90 detections in the SRPA. If the Sr-90 is actually in the samples, then it is expected that gross beta results would be elevated, confirming the Sr-90 data. Gross beta results were similar to background. The anomalous detections of Sr-90 that occurred in TRA-08 could not be verified with gross beta since there was not enough water to sample in March 2006.

Gross alpha analysis was added for the March 2006 sampling event because of the sporadic recent radium-226 detections from the gamma spectrometry analysis. If Radium-226 was actually present in the sample, then it is expected that gross alpha results would be elevated, confirming the presence of Radium-226. Gross alpha results were all below the MCL of 15 pCi/L, with the maximum detected concentration of 6.64 pCi/L occurring in MIDDLE-1823. Except for MIDDLE-1823, all wells had gross alpha concentrations that were similar to background. The anomalous detections of Ra-226 that occurred

in the October sampling event could not be verified with gross alpha since Ra-226 was not detected in any samples from the March 2006 sampling event.

2.2.6 Field Measured Parameters

Temperature, pH, specific conductance, and dissolved oxygen were measured in the field at the time of sampling. These parameters are summarized in Table 2-5 for the FY 2006 sampling events.

Table 2-5. Field measured parameters for FY 2006 sampling events.

PW-9	3/23/2006	15.5	8.16	0.507	3.41

NR= no reading
NS= not sampled

The dissolved oxygen readings indicate that oxidizing conditions exist in most of the perched wells. However, dissolved oxygen readings were not taken from TRA-1933 and TRA-1934 because these wells have hydrocarbon contamination that could negatively impact the sensor. Specific conductance measurements ranged from 0.424 to 0.904 mmhos/cm, with the highest value in Well USGS-054. The pH values were relatively consistent at 7.27 to 8.16.

The dissolved oxygen readings indicate that oxidizing conditions exist in the SRPA. Specific conductance measurements ranged from 0.332 to 0.633 mmhos/cm, with the highest value in Well TRA-07. The pH values were relatively consistent at 7.6 to 8.0. The dissolved oxygen, specific conductance, and pH values are consistent with previous measurements.

2.3 Petro Trap and Interface Probe Monitoring

Petro traps (Figure 2-9) were installed in perched water wells PW-13, TRA-1933, and TRA-1934 to collect free-phase product floating on the water, as recommended in the response to the first five-year review report (DOE-ID 2005). The floating product is probably the result of a diesel No. 2 spill that occurred in the late 1970s/early 1980s (INEL 1994). Petro traps were checked monthly as part of maintenance activities that included the measurement of the water level and free-phase product level using an interface probe, removal of collected free-phase product, and adjustment of the petro trap depth (Table 2-6).

The petro traps use a hydrophobic filter, allowing the diesel to pass through the filter and into a collection canister. The filter is mounted on a guide arm, allowing the filter to change position with changes in water level. The filter is attached to a float, keeping the filter above the perched water level. The guide arm allows the filter/float to travel up to 2 ft to accommodate changes in the water level. Petro traps are emptied by removing the trap from the well and emptying the collection canister through the drain valve. The trap can then be reinstalled, and any adjustments to the required depth due to changes in the water level can be completed. If measurable free-phase product thicknesses were noted in the well, then the trap was reinstalled and removal of the trap was repeated until the measurable thickness was reduced to zero or as often as time permitted.

a. Measurements are from the measuring point.

b. The petro trap in PW-13 was removed on 04/06/05 and reinstalled on 04/14/05.

c. The water level was only recorded during quarterly measurements.

2.3.1 PW-13

The petro trap in Well PW-13 was installed on November 11, 2004, per the manufacturer's guidelines. The free-phase product thickness and free-phase product recovery since the installation of the petro trap in Well PW-13 is displayed in Figure 2-10. Table 2-6 presents the recorded water levels, free-phase product thicknesses, and volume of free-phase product removed from PW-13. Figure 2-11 is a graphical representation of free-phase product thickness over time and volume removed. A total volume of approximately 53.45 L of free-phase product has been removed from the petro trap in PW-13 during routine maintenance. The volume of free-phase product has oscillated during the period in which the petro traps have been in the well.

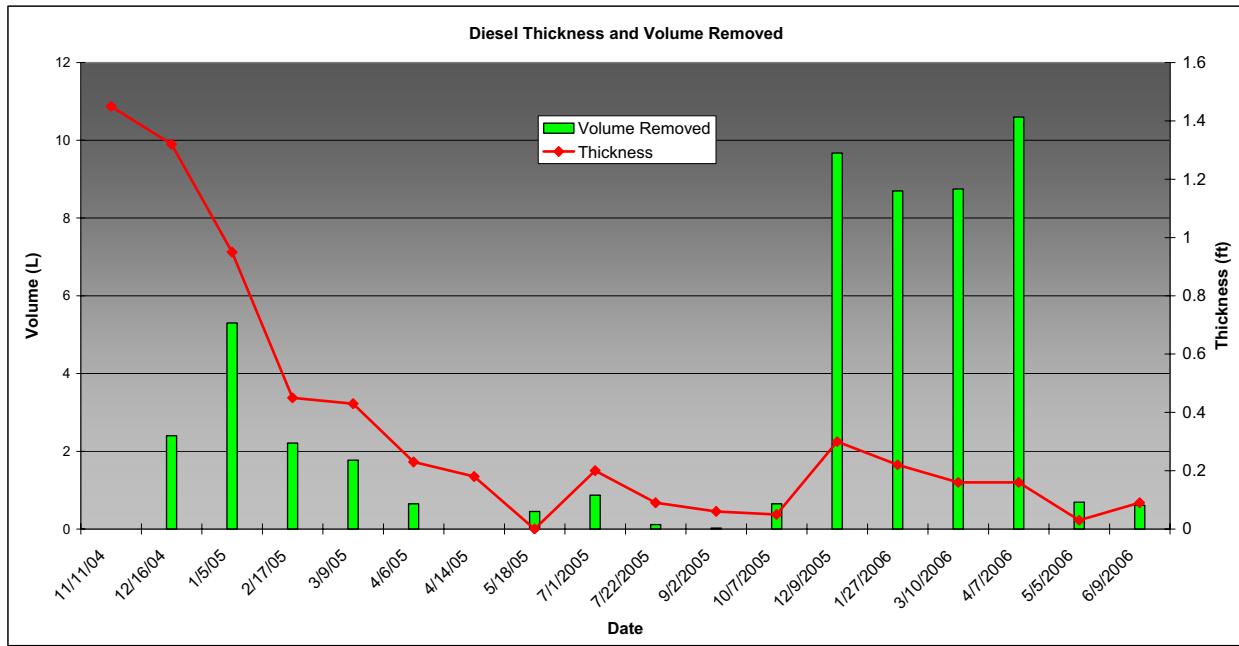

Figure 2-10. Free-phase product thickness and volume removed from PW-13.

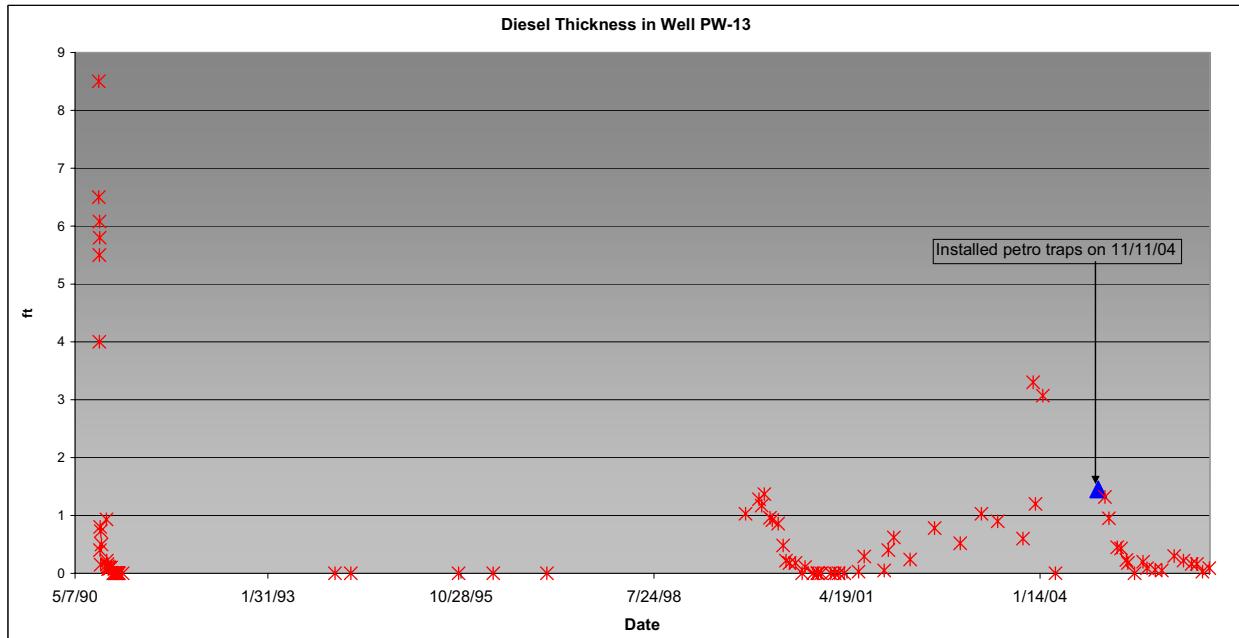

Figure 2-11. Free-phase product thicknesses over time in PW-13.

2.3.2 TRA-1933

The petro trap in Well TRA-1933 was installed on November 11, 2004, per the manufacturer's guidelines. Since the initial measurement taken during the November installation of the petro trap, only once (December 2005) has a measurable thickness of diesel been recorded in TRA-1933. The volume of free product removed during maintenance has been less than the first maintenance period in November 2004 (Table 2-6). A total volume of approximately 1.42 L of free-phase product was removed from TRA-1933 between July 2005 and July 2006.

2.3.3 TRA-1934

The petro trap in Well TRA-1934 was installed on January 5, 2005, per the manufacturer's guidelines. No measurable thickness of free-phase product has been noted in this well, nor has any volume of free-phase product been collected by the petro trap (Table 2-6).

2.3.4 Discussion of Petro Trap and Interface Probe Monitoring

The limited data indicate that the petro trap in PW-13 is impacting the thickness of free-phase product noted in the well. Free-phase product thickness has shown an overall decrease since the trap was installed in November 2004 (Figure 2-10). The period that the petro trap has been installed and maintained is limited in relation to the (approximate) 15-year history of this well. Historically, the free-phase product thicknesses (Figure 2-11) in PW-13 have varied substantially over time, with thickness decreasing to 0 with no remediation. The natural cycling of free-phase product in the subsurface could also be affecting the free-phase product thickness noted during maintenance. In contrast to free-product thickness, the volume of free product removed appears to be cyclic and not directly related to product thickness.

Well TRA-1933 has shown only limited free-phase product accumulation and only one instance of measurable thickness. The lower free-phase product volumes and thicknesses are probably due to the greater distance from the original release location, attenuation of the free-phase product, or decreased connectivity to pockets of free-phase product.

Well TRA-1934 has not shown a measurable thickness of diesel, nor has the petro trap collected any free-phase diesel. This location is farthest from the diesel source, located approximately 60 ft northeast of PW-13 (Figure 2-12).

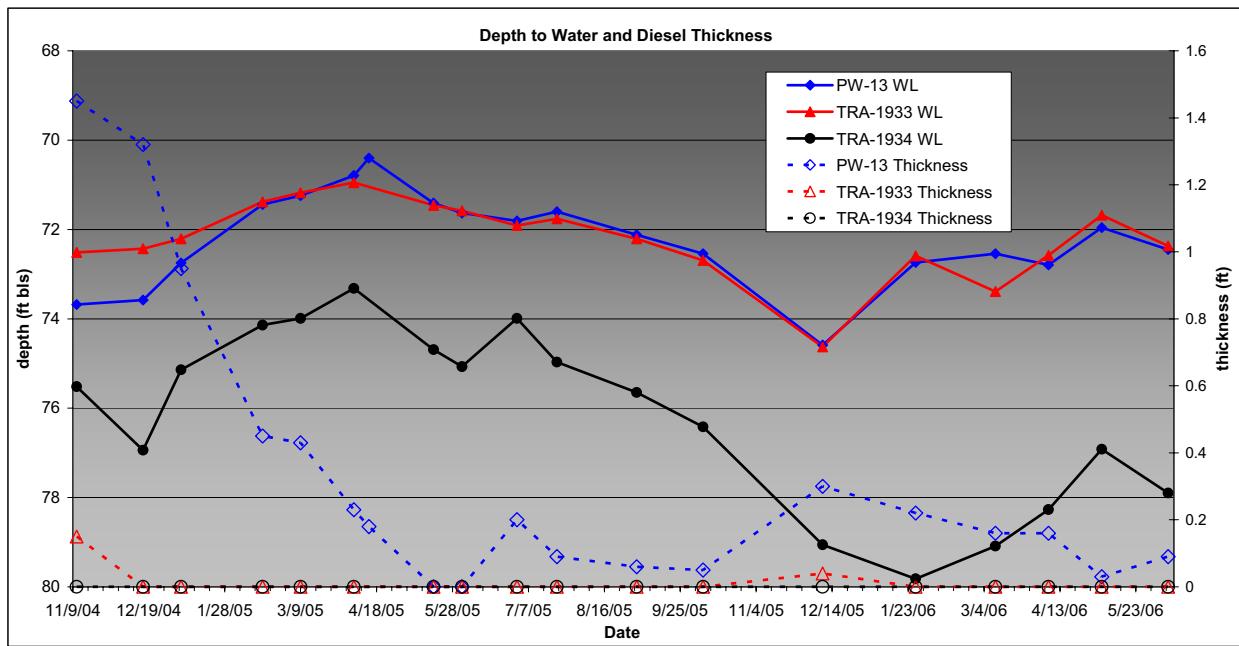

Figure 2-12. Water levels and free-phase product thicknesses in PW-13, TRA-1933, and TRA-1934.

3. RECOMMENDATIONS

Continued groundwater monitoring is recommended to be completed annually, rather than at the current twice-a-year sampling frequency identified in the WAG 2 groundwater monitoring plan (DOE-ID 2004a).

It is recommended that interface probe monitoring and the free-phase product recovery with the petro traps should continue for one more year at a monitoring frequency of 3 months instead of the current monthly rate. If current recovery trends continue, then the petro traps should be removed from TRA-1933 and TRA-1934.

Appendix A

Analytical Results

Appendix A

Analytical Results

This appendix presents the analytical data collected as a result of groundwater sampling at Waste Area Group (WAG) 2 during October 2005 and March 2006. Also included is data for a special sampling event for the Highway-3 well, conducted in January 2006. The analytes and analytical methods are summarized in Table A-1. Complete data are presented in Tables A-2, A-3, and A-4 as well as on the compact disc located in the back cover of this report. In the data tables, sample and duplicate samples are denoted by the number in front of the two-letter analytical code at the end of the field sample number with a “1” referring to the sample and “2” referring to a duplicate. For example, TRA43401RB and TRA43402RB refer to the sample and duplicate, respectively, for Strontium-90 at USGS-054.

Table A-1. Analytes and method codes.

Analyte	Method Code	Method Description
Gamma Spec	HAS	Radiochemistry by DOE EML HASL 300
Diesel Range Organics	SW8015	Non-Halogenated Volatile Organics
Gasoline Range Organics	SW8015B	Non-Halogenated Volatile Organics
Tritium	LSC	Liquid scintillation
Chromium	E200.7	U.S. EPA Method 200.7: Inductively Coupled Plasma Emission
Sr-90 ^a	GFP	Gas Flow Proportional Counter
Sr-90	HAS	Radiochemistry by DOE EML HASL 300
Gross Alpha	931	Gross Alpha and Gross Beta
Gross Beta	931	Gross Alpha and Gross Beta

a. GFP was used in the October sampling event. HAS was used in the March sampling event.

Data qualifier flags used in this appendix are a consolidation of laboratory- and validation-assigned flags and are defined as follows:

Inorganics

- B—the result is less than the contract-required reporting limit but greater than or equal to the instrument detection limit.
- E—the post-digestion spike was outside the control limits.
- N—the matrix spike recovery was outside control limits.
- U—the analyte was not detected.

- UJ—the analyte was analyzed for, but it was not detected. The associated value is an estimate and might be inaccurate or imprecise.
- R—the accuracy of the data is so questionable that it is recommended that the data not be used. The “R” flag overrides all other applicable flags.

Radiological Qualifier Flags

- J—the associated value is estimated. The result might not be an accurate representation of the amount of activity actually present in the sample.
- R—the accuracy of the data is so questionable that it is recommended that the data not be used. The “R” flag overrides all other applicable flags.
- U—the radionuclide is not considered present in the sample (i.e., nondetect).
- UJ—the radionuclide might or might not be present, and the result is considered highly questionable. The associated value is an estimate and might be inaccurate or imprecise. The result is considered a nondetect for project data interpretation purposes.

Table A-2. Data for October 2005 Waste Area Group 2 groundwater sampling.

Sample Results**

Appendix B

Quality Assurance/Quality Control Sample Results

B-1. QUALITY ASSURANCE/QUALITY CONTROL SAMPLING

The purpose of collecting and analyzing quality assurance/quality control samples is to confirm the achievement of project objectives and data quality objectives. The overall objectives associated with Waste Area Group 2 annual groundwater monitoring are discussed in the groundwater monitoring plan (DOE-ID 2004). The overall objectives and quality assurance or quality control sample results for the Fiscal Year (FY) 2006 sampling effort are discussed in the following subsections.

B-1.1 Precision and Accuracy

The spatial variations in the concentrations of contaminants at individual sites create sampling variability. Additional variability, called measurement error, occurs during sample collection, handling, processing, analysis, quality evaluation, and reporting. Concentrations of contaminants reported represent the true concentrations in the media sampled plus the measurement error, which can be minimized but not eliminated. Although it might not be significant in many cases, it is important to assess the contribution of measurement error to the total error in individual investigations. The analytical results of quality control samples are used to estimate the accuracy and precision, the quantitative descriptions of measurement error, and the bias.

B-1.1.1 Overall Precision

Precision is a measure of the reproducibility of measurements under a given set of conditions. In the field, precision is affected by sample collection procedures and the natural heterogeneity of the matrix. Overall precision (field and laboratory) can be evaluated via duplicate samples collected in the field. Typically, greater precision is required for analytes with very low action levels that are close to background concentrations. Allowable laboratory precision for water samples is defined as having a relative percent difference (RPD) of less than or equal to 20%. Field precision is the difference between overall precision and laboratory precision. Table B-1 summarizes the precision for the FY 2006 round of groundwater monitoring. Using the following formula, the RPD was calculated only for those samples that had true positive values for both the initial sample and the field duplicate:

$$\text{RPD} = \frac{|S - D|}{S + D} \times 200 \quad (\text{B-1})$$

where

- S = sample
D = duplicate.

Table B-1. Overall precision for Fiscal Year 2006 analytical data.

Analyte	Units	Date	Sample	Duplicate	RPD
Chromium	ug/L	10/17/05	6.5	6.3	3.13
Chromium (unfiltered)	ug/L	10/17/05	6.5	6.5	0.00
Strontium-90	pCi/L	04/04/06	60.9	59.6	2.16
Strontium-90	pCi/L	10/17/05	28.9	ND	---
Gross Beta	pCi/L	04/04/06	94.4	101	6.76
Gasoline Range Organics	ug/L	03/22/06	80.2	84.7	5.46
Gasoline Range Organics	ug/L	10/25/05	103	115	11.01
Diesel Range Organics	mg/L	03/22/06	0.2	0.57	96.10
Diesel Range Organics	mg/L	10/25/05	0.98	0.89	9.63

RPD = relative percent difference

Samples in which the analyte is detected in both the sample and the duplicate are shown in Table B-1. The precision for the data in Table B-1 is generally acceptable, but there are a couple of notable exceptions. The data in Table B-1 show that the RPD exceeds 20% for one of the two diesel range organics analyses. This could reflect sample variability since the concentrations are relatively low. The Sr-90 results from October 2005 show a large inconsistency, but the March 2006 data had an acceptable RPD. The large difference in the results for Sr-90 for the October 2005 data indicates a laboratory QA/QC problem. Laboratory problems could explain the unusual Sr-90 results for TRA-08 and the Highway-3 well. This is also indicated by the results for re-sampling of the Highway-3 well in January 2006.

B-1.1.2 Overall Accuracy

Accuracy is a measure of bias in a measurement system. Accuracy is affected by the methods used for sample preservation, sample handling, field contamination, and sample matrix. The effects of the first three are evaluated using the field blank, trip blank, and equipment rinsate results. The presence of a contaminant in the field blank, trip blank, or rinsate reveals that cross-contamination has occurred.

Laboratory accuracy is ensured through the use of standard methods and calibration standards from the National Institute of Standards and Technology. All instrumentation is calibrated before use per the procedures outlined in the analytical methods required by the Idaho National Laboratory (INL) Sample and Analysis Management (SAM) statements of work. Laboratory accuracy is assessed through the use of matrix spikes and laboratory control samples. The number of laboratory quality control samples is specified in the analytical methods employed in the INL SAM statements of work. Evaluation criteria for the quality control samples are specified in data-validation technical procedures administered by INL SAM. For samples analyzed in accordance with Environmental Protection Agency (EPA) Contract Laboratory Program protocol, validation is also performed in accordance with that protocol. For the FY 2006 data set, the overall accuracy of the analyses is acceptable.

B-1.1.3 Representativeness

Representativeness is a qualitative parameter that expresses the degree to which the sampling and analysis data accurately and precisely represent the characteristic of a population parameter being measured at a given sampling point or for a process or environmental condition. Representativeness is

evaluated by determining whether measurements were accurate and the samples represent actual concentrations in the aquifer.

For the FY 2006 sampling activity, all measurements were made according to established EPA and INL SAM protocol. Trained personnel followed established INL procedures to collect the physical samples.

B-1.1.4 Comparability

Comparability is a qualitative characteristic that refers to the confidence with which one data set can be compared to another. At a minimum, comparable data must be obtained using unbiased sampling designs. If sampling designs are biased, the reasons for selecting another design should be well documented. Data comparability for this sampling activity was ensured through the following efforts:

- All data sets contained the same variables of interest
- All measurements have been performed and results reported using common units
- Similar analytical procedures and quality assurance measures have been used
- All field and laboratory instrumentation had detection limits that were similar to or better than those historically employed
- Established INL procedures were followed to collect samples
- Wells selected for sampling are identical to those chosen historically.

Sampling rounds are conducted at approximately the same time of year in an effort to negate any effect that changes in groundwater levels (due to snowmelt and runoff) may have on the data.

B-1.2 Data Validation

Method data validation is the process whereby analytical data are reviewed against set criteria to ensure that the results conform to the requirements of the analytical method and any other specified requirements. Laboratory data for the October 2005 sampling event were validated to level A and the March 2006 laboratory data were validated to level B according to established INL SAM and EPA protocols. The limitations and validation reports were transmitted to the regulatory agencies in December 2005, January 2006, and June 2006. No major problems were identified during this method validation process.
